}
```

```
while( fgets( riga, MAXRIGA, f ) != NULL )
```

# Deadlock

## Deadlock avoidance techniques

Stefano Quer, Pietro Laface, and Stefano Scanzio

## Deadlock avoidance

- ❖ Deadlock **avoidance** techniques force the processes to provide (a priori) additional information about the requests they will perform during their execution
  - Each process must indicate how many resources of all types it will need to terminate its task
  - This information allows a process scheduling order so that there is the guarantee of no deadlock
    - If granting immediately a requested resource to a process can cause deadlock, the process is forced to wait (by not assigning the resource to the process)

# Deadlock avoidance

## ❖ The main algorithms

- differ in the amount and type of information required
  - The simplest model imposes that all processes declare the maximum number of resources of each type that they will need
- generally reduce the use of resources and the efficiency of the system
- are based on the concept of **safe state** and **safe sequence**

# Safe state

## Safe state

The system is able to

- Allocate the required resources to all processes
- Prevent the occurrence of a deadlock
- Find a safe sequence

## Safe sequence

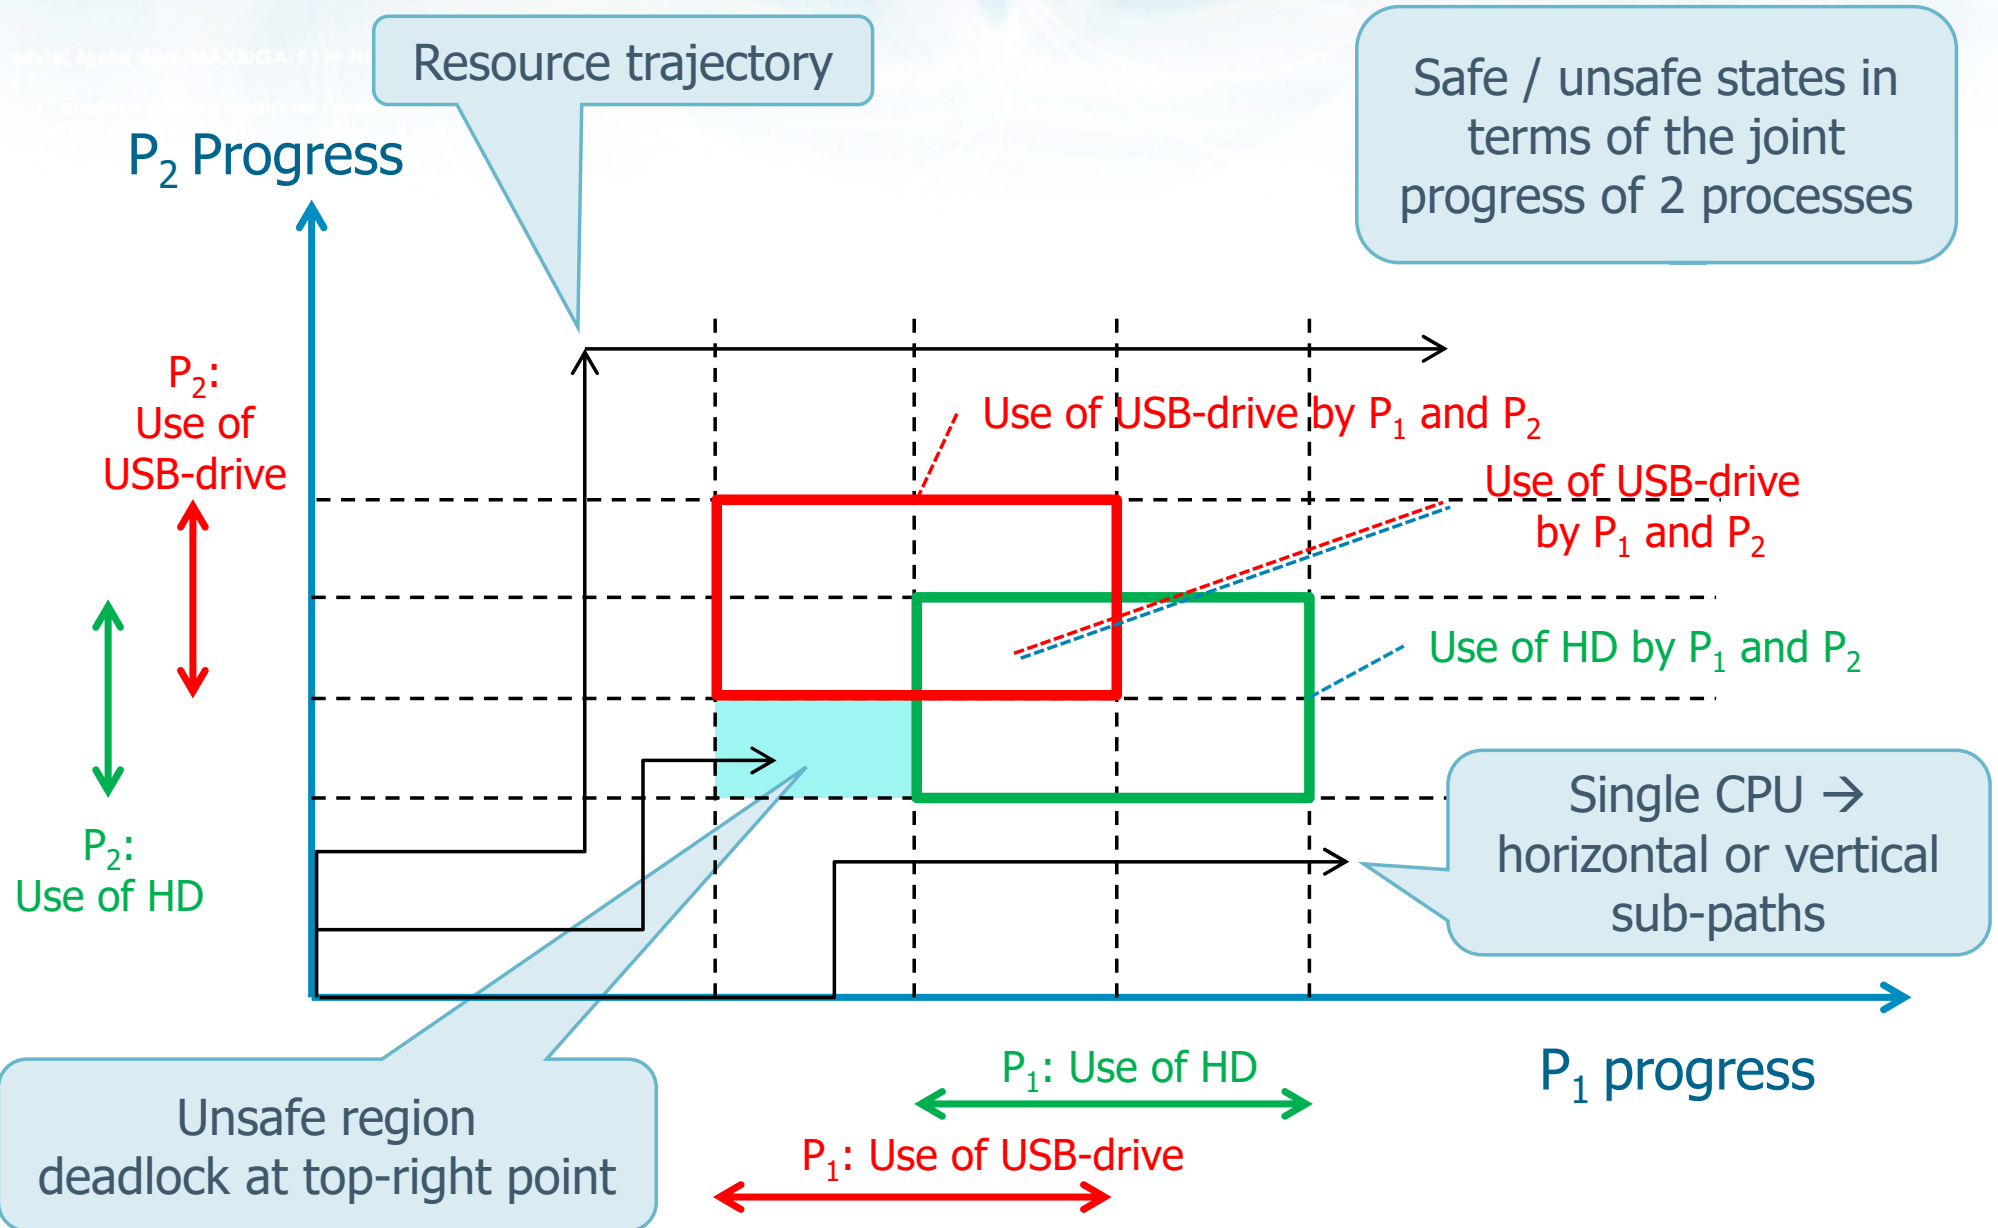

A sequence of process scheduling  $\{P_1, P_2, \dots, P_n\}$  such that for each requests that could be performed by any  $P_i$ , the request can be satisfied by using the currently available resources and the other resources released by processes  $P_j$  with  $j < i$

A state is said **unsafe** if it is not safe.

An unsafe state is not necessarily a deadlock state. It can leads to a deadlock state in case of standard behavior.

# Joint progress of two processes

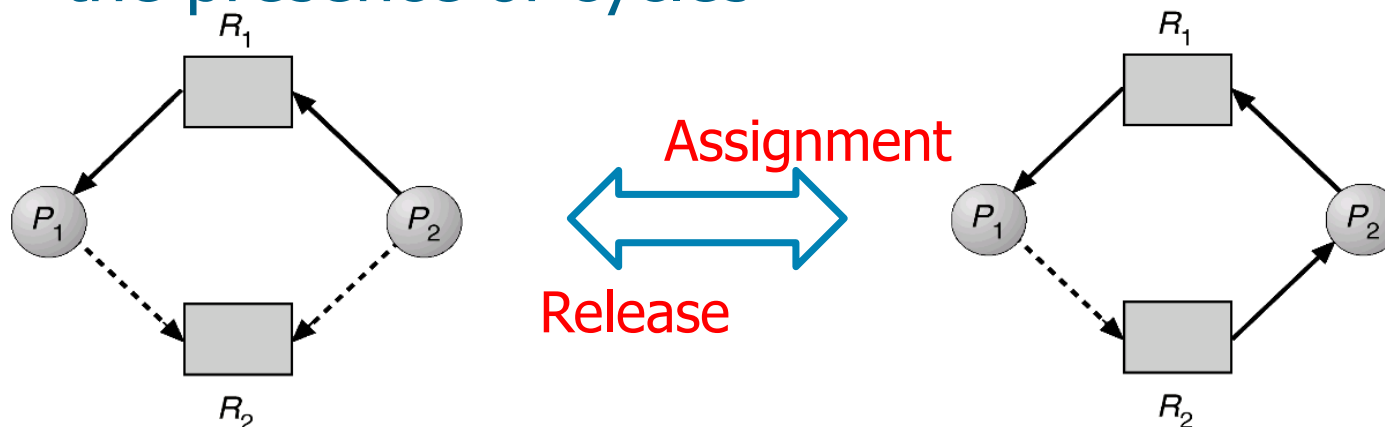

# Strategies

- ❖ To avoid a deadlock, one must ensure that the system remains always in a safe state
  - Initially the system is in a safe state
  - Each new resource request
    - will be granted **immediately**, if this allows the system to remain in a **safe state**
    - **otherwise**, granting the request will be **delayed**; the process that performed the request is forced to wait
- ❖ There are two classes of strategies
  - For resources having unitary instances
  - For resources having multiple instances

## Algorithm for resources with a single instance

- ❖ Based on the determination of cycles, using the claim-for graph
  - All requests must be a priori declared
  - they are represented by claim arcs  $---\rightarrow$
- ❖ At a time a request is performed
  - the corresponding claim arc is transformed into an assignment arc
  - Before the request is satisfied, the algorithm verify the presence of cycles

## Algorithm for resources with a single instance

- If no cycle is present, the conversion of the arc is performed and the resource assigned
- Otherwise, the assignment of the requested resource would bring the system into an unsafe state. For this reason it is postponed
- ❖ Each time a resource is released
  - the assignment arc is transformed into a claim arc (to manage any subsequent request)

## Algorithm for resources with multiple instances

- ❖ Verify the state of the system to understand if the available resources are sufficient to complete all processes based on
  - ❖ the number of resources available to the system,
  - ❖ number of resources allocated, and
  - ❖ max number of resource that the process may need
- ❖ Each process
  - must declare in advance its maximum number of resources it may need
  - when it requests a resource, it can be blocked for a limited amount of time
  - must guarantee to return an allocated resource in a finite amount of time

## Algorithm for resources with multiple instances

### ❖ Banker's Algorithm (Dijkstra, [1965])

#### ➤ It consists of two parts

- Verifies that the current state is safe
- Verifies whether the new request can be immediately granted allowing the system to remain in a safe state
  - Simulates assigning the resource, and controls that a sequence of assignments exists that allows the system to satisfy all requests, possibly delaying the delivery of the resources for some of the requests.

### ❖ The algorithm uses the data structures listed in the following slide

# Algorithm for multiple instances

Given a set of:

- $n$  processes  $P_r$
- $m$  resources  $R_c$

Name	Dim.	Content and meaning
<b>finish</b>	$[n]$	finish[r] initially false (indicates $P_r$ has not compete)
<b>allocation</b>	$[n][m]$	allocation[r][c]=k $P_r$ owns k instances of $R_c$
<b>max</b>	$[n][m]$	max [r][c]=k $P_r$ can ask a maximum of k instances of $R_c$
<b>need</b>	$[n][m]$	need[r][c]=k $P_r$ needs k additional instances of $R_c$ $\forall i \forall j$ need[i][j]=max[i][j]-allocation[i][j]
<b>available</b>	$[m]$	available[c]=k k resources $R_c$ are available

# Example

❖ By applying the banker algorithm, the underlying system is in a safe state?

➤ Safe sequence:  $P_1, P_3, P_0, P_2, P_4$

P	finish	allocation	max	need	available
		$R_0 \ R_1 \ R_2$	$R_0 \ R_1 \ R_2$	$R_0 \ R_1 \ R_2$	$R_0 \ R_1 \ R_2$
$P_0$	F	0 1 0	7 5 3		3 3 2
$P_1$	F	2 0 0	3 2 2		
$P_2$	F	3 0 2	9 0 2		
$P_3$	F	2 1 1	2 2 2		
$P_4$	F	0 0 2	4 3 3		

# Example

❖ Can the request of  $P_1$  (1, 0, 2) be satisfied?

- Yes ...
- System state evolution ...

P	finish	allocation	max	need	available
		$R_0 \ R_1 \ R_2$	$R_0 \ R_1 \ R_2$	$R_0 \ R_1 \ R_2$	$R_0 \ R_1 \ R_2$
$P_0$	F	0 1 0	7 5 3	7 4 3	3 3 2
$P_1$	F	2 0 0	3 2 2	1 2 2	2 3 0
$P_2$	F	3 0 2	9 0 2	6 0 0	
$P_3$	F	2 1 1	2 2 2	0 1 1	
$P_4$	F	0 0 2	4 3 3	4 3 1	

# Example

❖ The new state is safe or not?

➤ Safe sequence:  $P_1, P_3, P_0, P_4, P_2$

P	finish	allocation	max	need	available
		$R_0 \ R_1 \ R_2$	$R_0 \ R_1 \ R_2$	$R_0 \ R_1 \ R_2$	$R_0 \ R_1 \ R_2$
$P_0$	F	0 1 0	7 5 3	7 4 3	2 3 0
$P_1$	F	3 0 2	3 2 2	0 2 0	
$P_2$	F	3 0 2	9 0 2	6 0 0	
$P_3$	F	2 1 1	2 2 2	0 1 1	
$P_4$	F	0 0 2	4 3 3	4 3 1	

Same initial state

## Example

- ❖ Can the request of  $P_4$  (3, 3, 0) be satisfied?
  - No ... there is not availability (-> wait)
- ❖ Can the request of  $P_0$  (0, 3, 0) be satisfied?
  - No ... the resulting state is not safe

P	finish	allocation	max	need	available
		R <sub>0</sub> R <sub>1</sub> R <sub>2</sub>	R <sub>0</sub> R <sub>1</sub> R <sub>2</sub>	R <sub>0</sub> R <sub>1</sub> R <sub>2</sub>	R <sub>0</sub> R <sub>1</sub> R <sub>2</sub>
P <sub>0</sub>	F	0 1 0	7 5 3	7 4 3	2 3 0
P <sub>1</sub>	F	3 0 2	3 2 2	0 2 0	
P <sub>2</sub>	F	3 0 2	9 0 2	6 0 0	
P <sub>3</sub>	F	2 1 1	2 2 2	0 1 1	
P <sub>4</sub>	F	0 0 2	4 3 3	4 3 1	

# Banker's algorithm

## ❖ Verification of a request from $P_i$

```
if
   $\forall_j \text{ Request}[i][j] \leq \text{Need}[i][j]$  (otherwise WAIT)
  AND
   $\forall_j \text{ Request}[i][j] \leq \text{Available}[j]$  (otherwise ERROR)
  THEN
     $\forall_j \text{ Available}[j] = \text{Available}[j] - \text{Request}[i][j]$ 
     $\forall_j \text{ Allocation}[i][j] = \text{Allocation}[i][j] + \text{Request}[i][j]$ 
     $\forall_j \text{ Need}[i][j] = \text{Need}[i][j] - \text{Request}[i][j]$ 

    if the resulting state is safe
      this new state is confirmed
    Else
      the previous state is restored (and WAIT)
```

# Banker's algorithm

## ❖ Verify whether a state is safe or unsafe

1.  
 $\forall i \forall j \text{ need}[i][j] = \text{max}[i][j] - \text{allocation}[i][j]$   
 $\forall i \text{ finish}[i] = \text{false}$
2.  
Find a process  $P_i$  such that  
 $\text{finish}[i] = \text{false}$  AND  $\forall j \text{ need}[i][j] \leq \text{available}[j]$   
If no such  $i$  is found goto step 4
3.  
 $\forall j \text{ available}[j] += \text{allocation}[i][j]$   
 $\text{finish}[i] = \text{true}$   
goto step 2
4.  
if  $\forall i \text{ finish}[i] = \text{true}$  then  
system is in a safe state

## Exercise

- ❖ Can the request of  $P_1$  (1, 0, 1) be satisfied?
  - Yes ...
- ❖ Can the request of  $P_1$  (1, 0, 1) be satisfied?
  - No ... the resulting state is not safe

P	finish	allocation	max	need	available
		$R_0 \ R_1 \ R_2$	$R_0 \ R_1 \ R_2$	$R_0 \ R_1 \ R_2$	$R_0 \ R_1 \ R_2$
$P_0$	F	1 0 0	3 2 2		1 1 2
$P_1$	F	5 1 1	6 1 3		
$P_2$	F	2 1 1	3 1 4		
$P_3$	F	0 0 2	4 2 2		

## Exercise

❖ Are the following states safe or unsafe?  
(single resource problems)

P	F	A	M	N	AV
P <sub>0</sub>	F	3	9		3
P <sub>1</sub>	F	2	4		
P <sub>2</sub>	F	2	7		

... safe state

P	F	A	M	N	AV
P <sub>0</sub>	F	4	9		2
P <sub>1</sub>	F	2	4		
P <sub>2</sub>	F	2	7		

... unsafe state

# Banker's algorithm

## ❖ Complexity is

➤  $O(m \cdot n^2) = O(|R| \cdot |P|^2)$

## ❖ It is also based on unrealistic assumptions

- Processes must specify their demands in advance
  - The necessary resources are not always known
  - Also it is not known when a resource will be used
- Assumes that the number of resources is constant
  - Resources may increase or decrease due to transient or continuous failures
- It requires a fixed population of processes
  - The number of active processes in the system increases and decreases dynamically
