Lab 6

1

Type checking

- *Type expressions*
- *Symbol tables*
- *Implementation of a type-checker*

Lab 6

2

Type Checking

- *Type Checking* is the process used for the verification of types constraints:
 - Can be performed at compilation time (static check) or at execution time (dynamic check)
 - Dynamic types appear more often in interpreted languages, whereas compiled languages favor static types
 - Static checking is one of the main semantic tasks performed by a compiler

- Example of static check:

```
int a;
float b;

a = 2.5; /* Correct in c and c++, not correct in Java */
b = 1.5; /* Correct in c and c++, not correct in Java ( b=1.5f; )
```

Lab 6

4

Type Systems

- *Base types*
 - Programming languages typically include base types for:
 - △ numbers (int, float), characters, booleans
- *Compound and constructed types*
 - Programmers need higher level abstractions than the base types,
 - △ such as lists, graphs, trees, tables, etc.
 - Programming languages provide mechanisms to combine and aggregate objects and to derive types for the resulting objects
 - arrays, structures, enumerated sets, pointers
- A type system consists of a set of base types and a set of *type constructors*
 - array, function, pointer, struct (class, list, hash)
- Using base types and type-constructors each expression in a program can be represented with a *type expression*

Lab 6

5

Type-expressions

- Generally, types can be divided in :
 - Primitive types (*int, float, char*)
 - Composite types (*struct, union, pointer, array*)
- Primitive types comprises all the types necessary to the formalization of a given language (*int, float, char,...*) together with 2 special ones:
 - **void** : stating the absence of a type,
 - **type_error** : stating an error found during the type checking phase.
- **Type expressions**
 - A type-expression is either a base type or is formed by applying a type constructor to a type-expression

types
defined in C
language

Lab 6

7

Type Constructors

- Array: `array(I , T)`
 - I : size of the array
 - T : type expression
- Pointers: `pointer(T)`
- Product: `T1 X T2`
- Structure: `struct(T)`

Type constructor
examples referred to
the C language

Examples:

Declaration:

```
char v[10]
```

```
struct {
  int i;
  char s[5];
}
```

Type expression:

```
array(10, char)
```

```
struct((i x int) x (s x array(5, char)))
```

Lab 6

8

Type Constructors: Functions

- A function maps an element of its own domain to an element in its own range.
- Functions: $T_1 \rightarrow T_2$
 - T_1 : domain type
 - T_2 : range type
- The function `int* f(char a, char b)` is represented using the following type expression:
`(char x char) → pointer(int)`

Lab 6

9

Types Graph

- An effective way of representing type expressions consists in the use of graphs (trees or DAGs).

`(char x char) → pointer(int)`

Lab 6

10

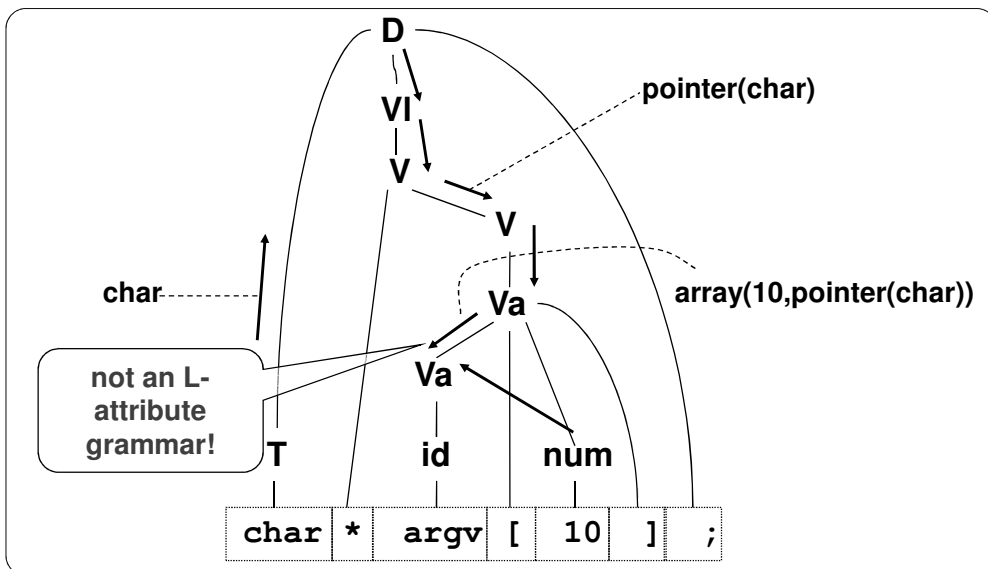

Construction of type-expressions

- A type checker for the C language could be implemented by means of the following grammar and semantic rules:

$D \rightarrow T VI \text{ ;}$
 $VI \rightarrow V$
 $VI \rightarrow VI_1 \text{ ; } V$
 $V \rightarrow '*' V_1$
 $V \rightarrow Va$
 $Va \rightarrow Va_1 \text{ [num]}$
 $Va \rightarrow id$

$v1.type = T.type$
 $v.type = v1.type$
 $v.type = v1.type$
 $v_1.type = \text{pointer}(v.type)$
 $va.type = v.type$
 $va_1.type = \text{array}(\text{num.val}, va.type)$
 $\text{put}(id.name, va.type);$

Construction of type-expressions (2)

Construction of type-expressions (rewriting of the prev. example)

$D \rightarrow T \text{ VI } ;'$
 $\text{VI} \rightarrow V$
 $\text{VI} \rightarrow \text{VI}_1 ;' V$
 $V \rightarrow P \text{ id } A$

$\text{V1.type} = \text{T.type}$
 $\text{V.type} = \text{V1.type}$
 $\text{V.type} = \text{V1.type}$
 $\text{P.base} = \text{V.type}$
 $\text{A.base} = \text{P.type}$
 $\text{put}(\text{id.value}, \text{A.type})$

$P \rightarrow \varepsilon$
 $P \rightarrow P_1 '*'$

$\text{P.type} = \text{P.base}$
 $\text{P.type} = \text{pointer}(\text{P}_1.\text{type})$
 $\text{P}_1.\text{type} = \text{P.base}$

$A \rightarrow \varepsilon$
 $A \rightarrow A_1 '[' \text{ num } ']'$

$\text{A.type} = \text{A.base}$
 $\text{A.type} = \text{array}(\text{num.val}, \text{A}_1.\text{type})$
 $\text{A}_1.\text{type} = \text{A.base}$

Lab 6

13

Types names

- In many languages it is possible to assign explicit names to types.
- Example:

```

typedef cell* link;      type link = ^cell;
link p;                 var p : link;
cell* q;                 var q : ^cell;
      
```
- Do variables p and q belongs to the same type? Answer depends on the approach used for checking it.
 - Structural equivalence.
 - Names equivalence
- In C structural equivalence is used while other languages (e.g., pascal) use names equivalence.

Lab 6

15

Structural Equivalence

- Two expressions are equal if:
 - They belong to the same primitive type
 - They are based on the application of the same types constructors to equivalent types.
- Using a tree based representation for type expression it is possible (and convenient) to use a recursive visit algorithm in order to verify the equivalence.

Lab 6

16

Type checker

- A type checker comprises a set of interoperating modules:
 - scanner: lexicon recognition
 - parser: checks the syntax and adds the semantic,
 - type-expression manager,
 - symbol table manager.

Lab 6

17

Symbol table

- Symbol tables associates values to names in order to make accessible the semantic information related to an identifier outside of the context where it has been declared.
- Information related to each name are used in order to verify the semantic correctness of identifiers usage within a program.

Designing a Symbol Table

- A symbol table can be implemented using different data structures:
 - Unordered Lists
 - Ordered Lists
 - Binary Tree
 - Hash Table
 - BTree ...
- This choice is based on the number of symbols to store, on the required performances and on the complexity of the code to be produced.

Symbol table: HashMap

```
import java.util.HashMap;
// Initializing the table
HashMap<String, String> symTable = new HashMap<String, String> ();

// Inserting entries: int a; float b;
symTable.put("a", "int");
symTable.put("b", "float");

// Get the value related to key "a"
String tipo = (String) symTable.get("a");
System.out.println(tipo);

// Deleting entry
symTable.remove("a");

// Deleting all entries
symTable.clear();
```

Lab 6

22

Type expression

- Type expressions (naturally represented by means of trees of types) can be transformed into a different internal representation (i.e., a Class).
- The management of type expressions requires
 - The definition of the data structure associated to each graph node
 - The definition of primitives that operate on nodes
- Nodes should be capable of representing the different type constructor and the base types as well.
- Primitives are required in order to hide the internal representation of nodes thus allowing the user to produce the easiest code possible.

Lab 6

23

Implementing type expressions

- Each node of a types graph comprises:
 - a tag, representing the type of node;
 - A set of different fields depending on the type of data to be stored

```
public class te_node {
    public int tag;    // BASE, ARRAY, POINTER, ...
    public int size;  // Number of elements in array
    public int code;  // Base type: INT, CHAR, FLOAT, ...

    // Only for structs
    public String name; // Struct name

    // Left and right children
    private te_node left, right;
}
```

Lab 6

24

Implementing type expressions

- The module charged to manage Type Expressions should offer the following primitives:

```
public class te_node {
    public int tag;
    ...
    public static te_node te_make_base(int code);
    public static te_node te_make_pointer(te_node base);
    public static te_node te_make_array(int size, te_node base);

    // Only for structs and functions
    public static te_node te_make_product(te_node l, te_node r);
    public static te_node te_make_name(String name);
    public static void te_cons_struct(te_node str, te_node flds);
    public static te_node te_make_fwdstruct(String name);
    public static te_node te_make_struct(te_node flds, String n);
    public static te_node te_make_function(te_node d, te_node r);
}
```

Lab 6

25

Type checker: complete grammar

```

S ::= /* empty */
    | S Decl ';'
;
Decl ::= T Vlist
        | TYPEDEF T ID
;
T ::= TYPE
    | STRUCT ID '{' SFL '}'
    | STRUCT '{' SFL '}'
    | STRUCT ID
;
SFL ::= Field
    | SFL Field
;
Field ::= T Vlist
;
Vlist ::= V
        | Vlist ',' V
;
V ::= Ptr ID Array
;
Ptr ::= /* empty */
        | Ptr '*'
;
Array ::= /* empty */
        | Array SO NUM SC
;

```

Lab 6

27

Type checker: Semantic

```

Decl ::= T Vlist S;
T ::= TYPE:t;          {: RESULT=te_make_base(t); :}

Vlist::= V:t          {: RESULT=(te_node)t; :}
        | Vlist:t',' NT0 V {: RESULT = t; :}
;
NT0 ::= /* empty */ {: RESULT=(te_node) stack[top-1]; :}
;
V ::= Ptr ID:a Ary:t   {: add_var(a, t);
                       RESULT=(te_node) stack[top-3]; :}
;
Ptr ::= /* empty */   {: RESULT=(te_node) stack[top]; :}
        | Ptr:p '*'   {: RESULT=te_make_pointer(p); :}
;
Ary ::= /* empty */   {: RESULT=(te_node) stack[top-1]; :}
        | Ary:a SO NUM:b SC {: RESULT=te_make_array(b, a); :}
;

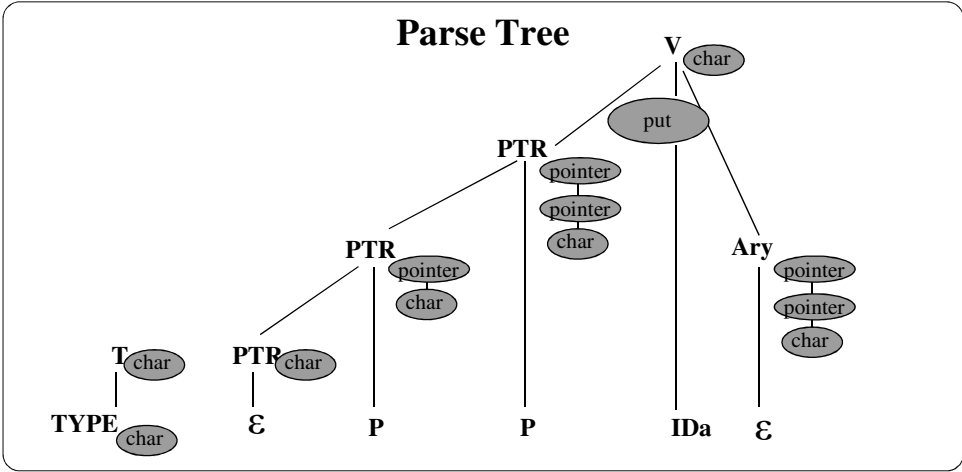

```

Lab 6

28

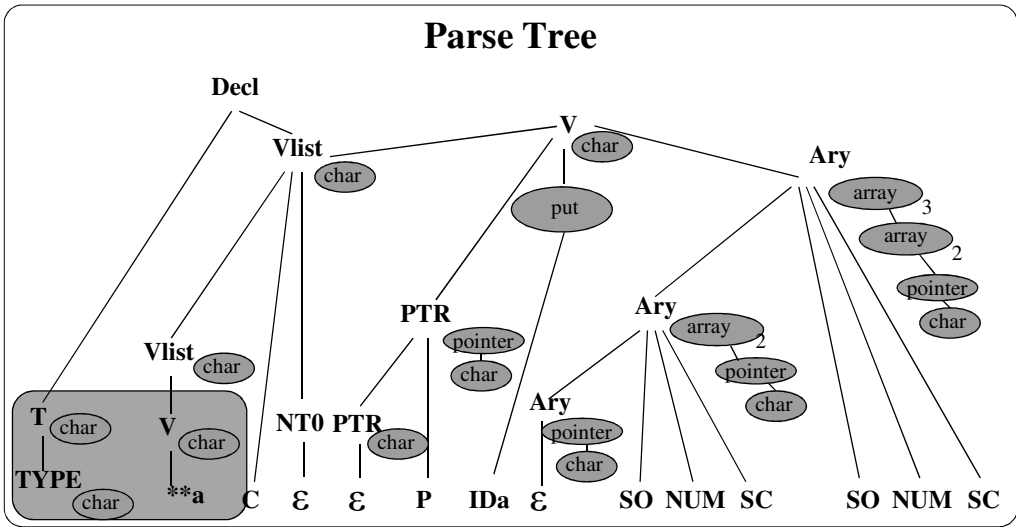

Type checker: Semantic (II)

```
char **a, *b[2][3];
```

Type checker: Semantic (III)

```
char **a, *b[2][3];
```

Exam 1

```
// Definition of the product type:  
( taste: 12 , perfume: 8 ) -> wine  
( taste: 10, transparency:2 ) -> honey  
.  
// Description of the products  
wine: * taste, + perfume = barbera DOC;  
wine: * taste, * perfume = barolo di annata;  
wine: - taste, / perfume = a stinky wine;  
honey: * taste, * transparency = acacia honey;
```

Thesis

List: <https://www.skenz.it/ss/theses>
About myself: <https://www.skenz.it/ss>

About myself

- 2004 – Finished my studies at Politecnico di Torino in Computer Science at DAUIN
- 2008 – Ph.D. at DAUIN in Automatic Speech Recognition
 - In collaboration with Loquendo (now Nuance)
 - Specifically on Artificial Neural Networks and classification algorithms
- 2009 – Research Fellow at IEIT (institute of the CNR)
 - CNR is the biggest Italian research organization
 - IEIT institute is in Politecnico di Torino (near room 12, 4° floor)
- 2012 – Won a permanent position at CNR as a Researcher

Lab 6

33

Current research activities

Industrial Automation

- Communication protocols
 - Industrial networks require a high degree of determinism
 - Easy to obtain in wired networks, but in wireless ones ???
- Real-time operating system (Sometimes most of the indeterminism is inside the PC)
 - Use of real-time extensions of Linux kernel
 - Properly optimize the code (threads, kernel modules, communication between kernel and user spaces)
- Industrial Internet of Things (IIoT)

Lab 6

34

Current research activities

Industrial Automation

- Synchronization protocols
 - Nodes must have the same notion of time (μs precision or less)
 - It is a very complex argument that involves the network, operating system, hardware, control algorithms for clock correction, ...

- Machine learning applied to industry

- Complete list of research activities:
 - <https://www.skenz.it/ss/research>

- Collaborations with: Comau and Ferrero

Lab 6

35

Programming languages

- C/C++ for the fastest parts of the code (i.e., applications with real-time requirements)

- Python for post analysis of experimental data or to coordinate experiments

- Linux operating system, and in particular:
 - Linux bash shell
 - Threads
 - Processes

Lab 6
